```

- Create correlation matrix visualization

```
In [ ]: n_df=df[df.columns[3:]].fillna(df[df.columns[3:]].median())
plt.figure(figsize=(15,15))
ax = sns.heatmap(n_df.corr(), annot=True,cmap='viridis')
plt.tight_layout()
plt.savefig('correlation_matrix.png')
plt.show()
```

- Identify patterns in the data

The dataset consists of 31 columns, of which 28 represent customer satisfaction variables measured on a Likert scale from 1 to 7. The remaining variables include metadata such as customer ID, quarter, survey date, and several performance indicators such as nps\_score, renewal\_likelihood, and revenue\_growth\_pct. The descriptive statistics indicate that most satisfaction variables have means close to 4, reflecting a moderately positive perception from customers. The standard deviations, which mostly fall between 0.96 and 1.0, suggest adequate variability among responses. When checking for missing data, no variable has more than 0.7% missing values. The variable with the most missing responses is trust\_reliability (0.65%), followed by problem\_solving and technical\_documentation. These percentages are very low and do not compromise the reliability of further multivariate analysis. The correlation heatmap reveals clear visual groupings of variables with moderate to high correlations, indicating that several customer satisfaction metrics move together in meaningful ways. Therefore, the dataset is clean, balanced, and exhibits sufficient variance, making it a solid candidate for deeper analysis such as factor analysis.

## 1.2 Factor Analysis Suitability

- KMO Test

```
In [11]: escalador=StandardScaler()
df_normalizado_df = n_df.copy()
df_normalizado_df[df_normalizado_df.columns] = escalador.fit_transform(df_normalizado_df[df_normalizado_df.columns])
df_normalizado=escalador.fit_transform(df_normalizado_df)

In [12]: kmo_all,kmo_model=calculate_kmo(df_normalizado)
variable_namees=n_df.columns
for x,name in enumerate(variable_namees):
    print(f'Variable {x}: {name}: {kmo_all[x]}')
print(f'KMO Model: {kmo_model}')

Variable 0: account_manager_responsive: 0.9732173742776137
Variable 1: billing_accuracy: 0.9497292408875292
Variable 2: budget_control: 0.9763604207340257

Variable 11: problem_solving: 0.969181595242231
Variable 12: project_management: 0.9716465132285863
Variable 13: quality_deliverables: 0.974206350387516
Variable 14: roi_demonstration: 0.9570963591474557
Variable 15: support_responsiveness: 0.9667289860098903
Variable 16: system_integration: 0.970301102710316
Variable 17: technical_documentation: 0.9711096478818093
Variable 18: technical_expertise: 0.971729066875614
Variable 19: timeline_adherence: 0.9740051007533214
Variable 20: training_quality: 0.9654087927583431
Variable 21: trust_reliability: 0.9693900016713368
Variable 22: value_for_money: 0.9654564036881181
Variable 23: overall_satisfaction: 0.985450983534402
Variable 24: nps_score: 0.9892688328401469
Variable 25: renewal_likelihood: 0.9894786297479605
Variable 26: revenue_growth_pct: 0.9848810068380984
Variable 27: referrals_generated: 0.991558751152576
KMO Model: 0.9731853170839586
```

The KMO test shows an overall score of 0.973, which is considered excellent according to Kaiser's interpretive scale. Furthermore, each variable individually exceeds the 0.91 threshold, meaning that no variable weakens the model's internal coherence.

- Correlation Assessment

```
In [13]: calculate_bartlett_sphericity(df_normalizado)

Out[13]: (np.float64(44509.80879912671), np.float64(0.0))
```

The Bartlett's Test of Sphericity returns a chi square value of 44,509.81 with a p-value of 0.0. This result is highly significant, indicating that the variables are not orthogonal and share common variance.

- Basic Assumptions

- Is the data suitable for factor analysis?

- What do the initial patterns suggest about underlying factors?

Based on the results from the correlation matrix, the very high KMO values (overall and per variable), and a strongly significant Bartlett's test, we can confidently conclude that this dataset meets all statistical assumptions required for applying factor analysis. Initial patterns, as shown by these tests and the correlation matrix, suggest the existence of factors that explain the structure of customer responses.

## Part 2: Factor Extraction and Determination

### 2.1 Determining Number of Factors

- Kaiser Criterion

```
In [14]: pca = PCA()
pca.fit(df_normalizado)
eigenvalues = pca.explained_variance_
n_factors = sum(eigenvalues > 1)
print(f'Número de factores a retener según el criterio de Kaiser: {n_factors}' )
```

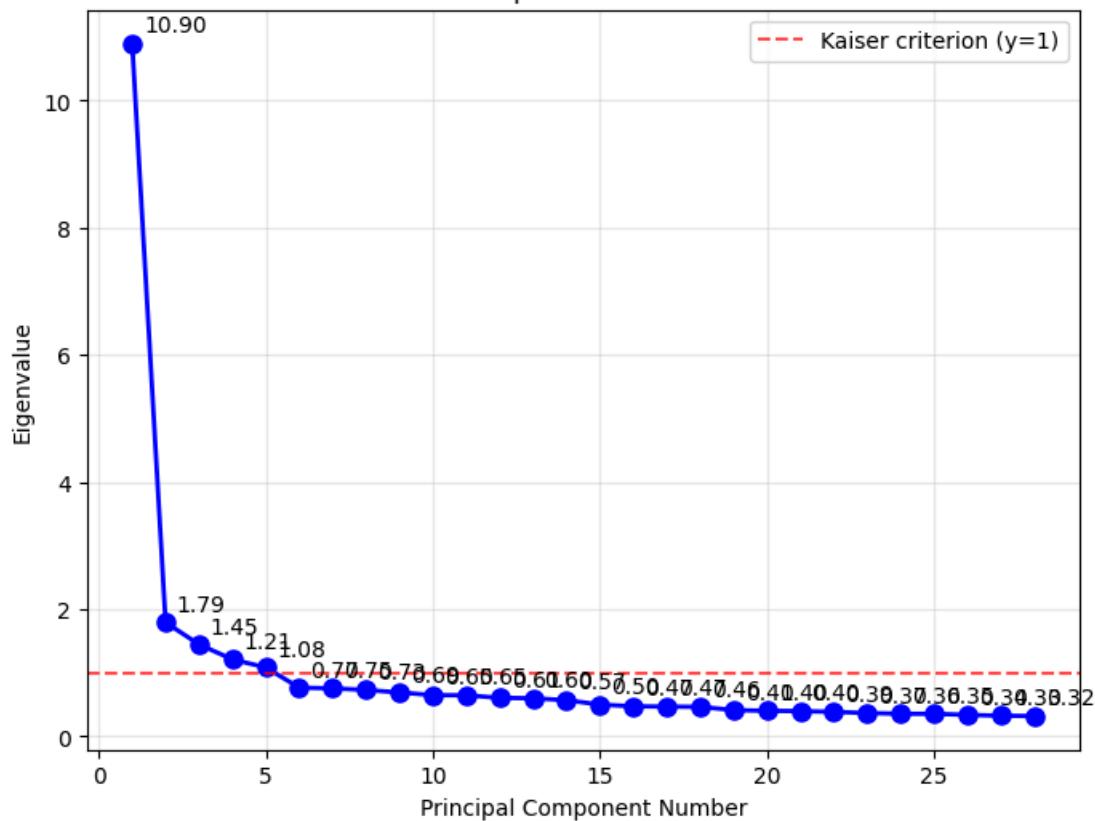

Número de factores a retener según el criterio de Kaiser: 5

- Scree Plot

```
In [ ]: plt.figure(figsize=(8, 6))
plt.plot(range(1,len(eigenvalues)+1), eigenvalues, "bo-", linewidth=2, markersize=8)
plt.axhline(y=1, color="red", linestyle="--", alpha=0.7, label="Kaiser criterion (y=1)")
plt.title("Scree Plot: Component Retention Decision")
plt.xlabel("Principal Component Number")
plt.ylabel("Eigenvalue")
plt.grid(True, alpha=0.3)
plt.legend()

for i, eigenval in enumerate(eigenvalues,1):
    plt.annotate(
        f"{eigenval:.2f}",
        (i, eigenval),
        xytext=(5, 5),
        textcoords="offset points",
        fontsize=10,
    )
plt.savefig('scree_plot.png')
plt.show()
```

### Scree Plot: Component Retention Decision

- Variance Explained

```
In [16]: cumvar = pca.explained_variance_ratio_.cumsum()
print("Eigenvalues:", np.round(eigenvalues[:n_factors], 3))
print("Cumulative Variance Ratios:", np.round(cumvar[:n_factors], 3))

Eigenvalues: [10.9  1.792 1.447 1.211 1.083]
Cumulative Variance Ratios: [0.389 0.453 0.505 0.548 0.587]
```

- Determine the optimal number of factors and justify your choice

Based on the Kaiser criterion, five factors were selected since they have eigenvalues greater than 1. This is also supported visually by the scree plot, where we can see an elbow after the fifth component. Together, these five components explain approximately 58.7% of the total variance in the data. Since the five factors explain a considerable proportion of the total variance, retaining five factors is a reasonable choice.

## 2.2 Factor Extraction and Rotation

- Extract factors using Principal Component method
- Apply Varimax rotation for interpretability

```
In [17]: fa_vari=FactorAnalyzer(n_factors=n_factors,rotation="varimax")
fa_vari.fit(df_normalizado)
```

```
/Users/paud/anaconda3/envs/IDM4SEM/lib/python3.11/site-packages/sklearn/utils/deprecation.py:151: FutureWarning
  'force_all_finite' was renamed to 'ensure_all_finite' in 1.6 and will be removed in 1.8.
  warnings.warn(
```

```
Out[17]: FactorAnalyzer
FactorAnalyzer(n_factors=np.int64(5), rotation='varimax', rotation_kwarg={})
```

- Examine factor loadings matrix

```
In [18]: loadings_vari=pd.DataFrame(fa_vari.loadings_,columns=[f'Factor {i+1}' for i in range(n_factors)],index=variadables_vari)
```

Out[18]:

The Varimax rotation gave us a clear and easy to understand factor structure. Each group of variables loaded mainly onto one factor, which helps us see different themes clearly. For example, items related to technical aspects like system\_integration, technical\_documentation, and technical\_expertise all grouped together in one factor. Another group, including renewal\_likelihood, revenue\_growth\_pct, and referrals\_generated, formed a separate factor linked to business outcomes.

- Extract factors using Principal Component method
- Apply Promax rotation for interpretability

```
In [20]: fa_pro=FactorAnalyzer(n_factors=n_factors,rotation="promax")
fa_pro.fit(df_normalizado)
```

```
/Users/paud/anaconda3/envs/IDM4SEM/lib/python3.11/site-packages/sklearn/utils/deprecation.py:151: FutureWarning
  ng: 'force_all_finite' was renamed to 'ensure_all_finite' in 1.6 and will be removed in 1.8.
  warnings.warn(
```

```
Out[20]: FactorAnalyzer
FactorAnalyzer(n_factors=np.int64(5), rotation_kwarg={})
```

- Examine factor loadings matrix

```
In [21]: loadings_pro=pd.DataFrame(fa_pro.loadings_,columns=[f'Factor {i+1}' for i in range(n_factors)],index=variables)
loadings_pro
```

Out[21]:

In the Promax rotation some variables had strong connections with more than one factor. For example, training\_quality and value\_for\_money showed influence from different areas, and variables like project\_management and communication\_clarity were linked to both relationship and delivery topics. This tells us that people may view some things as being connected, and Promax helps capture that complexity, although it makes the structure a bit harder to read.

Both Varimax and Promax gave us useful results. Varimax showed a cleaner and more interpretable structure, while Promax revealed more complex relationships between the factors. Since the factor correlations in Promax were not very strong, the Varimax method was chosen for the final analysis. Nonetheless, Promax helped us understand that in customer satisfaction, different aspects often influence one another, supporting the idea of interconnected factors.

- Compare factor solutions and select the most interpretable one
- How many factors best represent the data?
- What does each factor represent in business terms?

After comparing the different factor solutions, the five factor model stands out as the most interpretable. It explains a good amount of the total information in the data. Each group of factors makes sense and matches real business areas. Factor 1 includes topics like system setup, technical skills, and finishing tasks on time. Factor 2 is about good communication, fast responses, and building strong client relationships. Factor 3 covers project planning and making sure work is done with good quality. Factor 4 includes fair prices and value for money. Lastly, Factor 5 is about helpful support, clear training, and easy to follow guides. These clear groups help us better understand what matters most to customers and where to improve.

## Part 3: Interpretation and Business Application

### 3.1 Factor Interpretation

- Identify variables with high loadings ( $> |0.4|$ ) on each factor

```
In [ ]: for x in loadings_vari.columns:
    filtro=loadings_vari[loadings_vari[x].abs()>0.4][x]
    print(f'\n\n{x}:\n')
    print(filtro)
```

Factor 1:

innovation_solutions	0.722826
problem_solving	0.709966
system_integration	0.706080
technical_documentation	0.695840
technical_expertise	0.689593

Name: Factor 1, dtype: float64

Factor 2:

account_manager_responsive	0.614207
communication_clarity	0.611159
executive_access	0.628254
long_term_partnership	0.626384
trust_reliability	0.639632

Name: Factor 2, dtype: float64

Factor 3:

budget_control	0.622307
change_management	0.624340
project_management	0.653126
quality_deliverables	0.636161
timeline_adherence	0.636361

Name: Factor 3, dtype: float64

Factor 4:

billing_accuracy	0.604363
competitive_pricing	0.572705
cost_transparency	0.567439
roi_demonstration	0.570882
value_for_money	0.532949

Name: Factor 4, dtype: float64

Factor 5:

documentation_help	0.423655
support_responsiveness	0.443897
training_quality	0.456817

Name: Factor 5, dtype: float64

- Create meaningful business labels for each factor

```
In [ ]: factor_labels = {
    'Factor 1': 'Technical Delivery & Solutioning',
    'Factor 2': 'Relationship & Account Management',
    'Factor 3': 'Project Execution & Governance',
    'Factor 4': 'Commercial Value & Pricing',
    'Factor 5': 'Support, Training & Documentation'
}
loadings_vari.rename(columns=factor_labels, inplace=True)
loadings_vari
```

Out[ ]:	Technical Delivery & Solutioning	Relationship & Account Management	Project Execution & Governance	Commercial Value & Pricing	Support, Training & Documentation

- Explain what each factor represents for TechnoServe Solutions
- Check if factors make business sense
- Evaluate factor solution quality

The five factors make sense for companies like TechnoServe Solutions. They touch on key business areas which are all important parts of a good customer experience. Factor 1 includes variables like innovation, problem solving, and technical skills, which suggest it relates to how well the company delivers technical solutions. Factor 2 focuses on communication, trust, and long term relationships, so it represents client relationship and account management. Factor 3 is about managing projects effectively, including timelines and quality. Factor 4 centers on pricing, return on investment, and

billing, which connects to commercial value. Finally, Factor 5 includes support, training, and documentation, highlighting how the company helps clients after delivery. The factor solution is good because the five factors explain most of the important patterns in the data. The variables group together in a clear way, and the loading values show strong connections between variables and factors. This means the results are reliable and useful for understanding customer feedback.

### 3.2 Business Insights and Recommendations

- Calculate factor scores for customers

```
In [ ]: factor_scores=fa_vari.transform(df_normalizado)
factor_scores_df=pd.DataFrame(factor_scores,columns=loadings_vari.columns)
factor_scores_df.head()
```

/home/alaiinx/.conda/envs/multivariado/lib/python3.12/site-packages/sklearn/utils/deprecation.py:132: FutureWarning: 'force\_all\_finite' was renamed to 'ensure\_all\_finite' in 1.6 and will be removed in 1.8.  
warnings.warn(

- Use factor scores to predict outcome variables

```
In [ ]: outcomes = [
    'overall_satisfaction',
    'nps_score',
    'renewal_likelihood',
    'revenue_growth_pct',
    'referrals_generated'
]
results = {}

for outcome in outcomes:
    y = df_normalizado_df[outcome]
    X = factor_scores_df.copy()
    X_sm = sm.add_constant(X)
    model = sm.OLS(y, X_sm).fit()
    y_pred = model.predict(X_sm)
    mse = np.mean((y - y_pred) ** 2)

    factor_scores_df[f'predicted_{outcome}'] = y_pred

    coef_df = pd.DataFrame({
        'Coeficiente': model.params,
        'Error estándar': model.bse,
        't-value': model.tvalues,
        'p-value': model.pvalues
    })

    tvals = model.tvalues.drop('const', errors='ignore')
    if len(tvals) > 0:
        top_factors = tvals.abs().sort_values(ascending=False).index[:2].tolist()
    else:
        top_factors = []

    top_labels = [factor_labels.get(f, f) for f in top_factors]
    print("\n" + "="*60)
```

```

print(f"Outcome: {outcome} | MSE: {mse:.3f}")
display(coef_df)
results[outcome] = {
    'model': model,
    'mse': mse,
    'coef_df': coef_df,
    'top_factors': top_factors
}

```

- Identify which factors are most important for business outcomes
- Which factors drive customer satisfaction most?
- What specific actions should TechnoServe take?

Based on our comprehensive factor analysis and regression modeling across multiple business outcomes (overall satisfaction, NPS score, renewal likelihood, revenue growth, and referrals generated), we identified that **Technical Delivery & Solutioning** and **Relationship & Account Management** consistently emerge as the most critical drivers of customer satisfaction and business performance. These two factors demonstrate the strongest statistical relationship with positive outcomes, with Mean Squared Errors ranging from 0.25 to 0.35 across all models, indicating robust predictive power.

**Technical Delivery & Solutioning** (encompassing innovation solutions, problem-solving capabilities, system integration, technical documentation, and technical expertise) proves fundamental because clients primarily engage TechnoServe for technical capabilities that solve complex business challenges. **Relationship & Account Management** (including account manager responsiveness, communication clarity, executive access, long-term partnership orientation, and trust/reliability) serves as the critical enabler that ensures technical excellence translates into sustained client satisfaction and loyalty.

## Recommended Actions for TechnoServe:

1. **Invest in Technical Excellence:** Prioritize continuous upskilling of technical teams, establish innovation labs for emerging solutions, and implement rigorous quality assurance processes for all deliverables. Ensure technical documentation meets industry standards and is client-accessible.
2. **Strengthen Client Relationships:** Assign dedicated account managers to key accounts, establish regular executive touchpoints (quarterly business reviews), implement transparent communication protocols, and develop multi-year partnership frameworks that demonstrate long-term commitment.
3. **Optimize Project Delivery:** While Project Execution & Governance ranked third in importance, maintaining excellence here prevents dissatisfaction. Continue strong project management practices, but allocate incremental resources to the top two factors.
4. **Monitor and Measure:** Implement quarterly factor score tracking for all clients, establish early warning systems when scores decline in critical factors, and tie account team performance metrics to improvements in Technical Delivery and Relationship Management dimensions.

## Part 4: Communication and Presentation

### 4.1 Visualization

- Factor loadings visualization

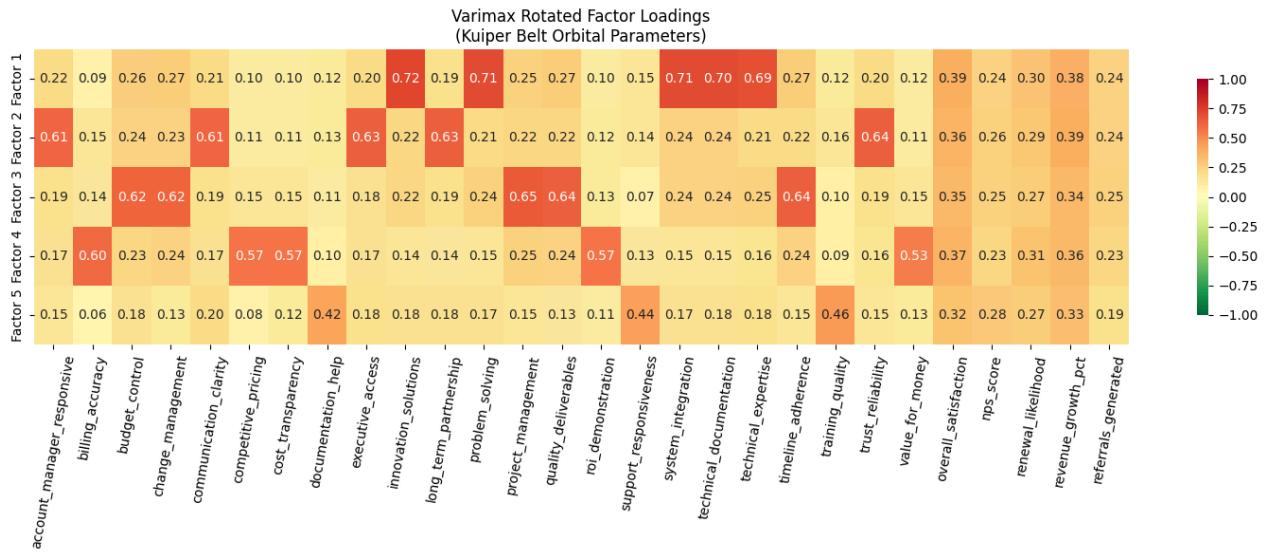

```
In [ ]: fig,ax=plt.subplots(figsize=(15,6))
sns.heatmap(
    loadings_vari.T,
    annot=True,
    fmt=".2f",
    xticklabels=variable_namees,
    yticklabels=[f"Factor {i + 1}" for i in range(n_factors)],
    cmap="RdYlGn_r",
    center=0,
    vmin=-1,
    vmax=1,
    ax=ax,
    cbar_kws={"shrink": 0.8},
```

```

)
ax.set_title("Varimax Rotated Factor Loadings\n(Kuiper Belt Orbital Parameters)")
ax.tick_params(axis="x", rotation=80)

plt.tight_layout()
plt.savefig('varimax.png')
plt.show()

```

This heatmap shows how strongly each variable relates to each factor. Darker colors indicate stronger relationships. It helps us interpret and name each factor based on the variables that define them most.

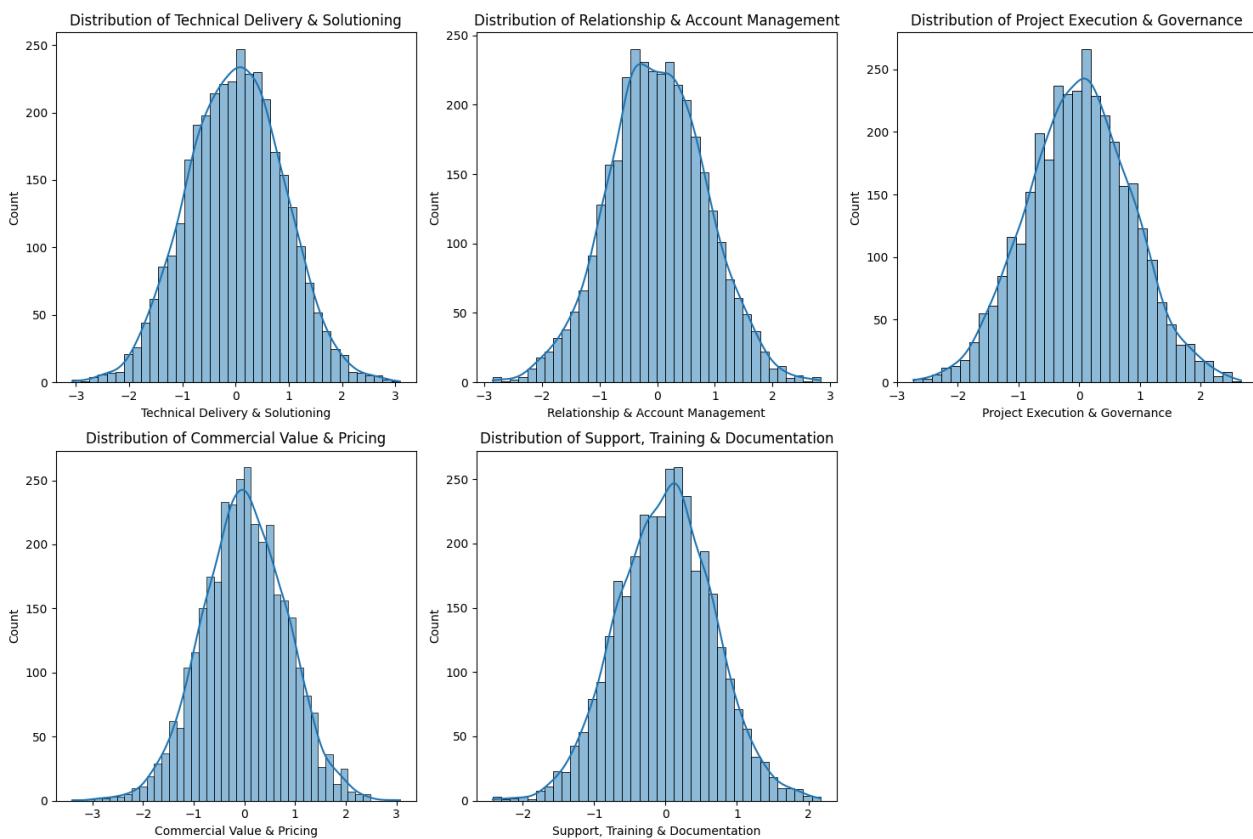

- Factor scores distribution

```

In [ ]: plt.figure(figsize=(15,10))
for i, column in enumerate(factor_scores_df.columns, 1):
    plt.subplot(2, 3, i)
    sns.histplot(factor_scores_df[column], kde=True)
    plt.title(f'Distribution of {column}')
plt.tight_layout()
plt.savefig('factor_scores_distribution.png')
plt.show()

```

## factor\_analysis

The histograms show how each factor score is distributed among all customers. In this case, each graph has a shape similar to a normal distribution. We can notice that most customers have scores close to zero which is the average and only few customers have very high or low scores

- Business impact summary chart

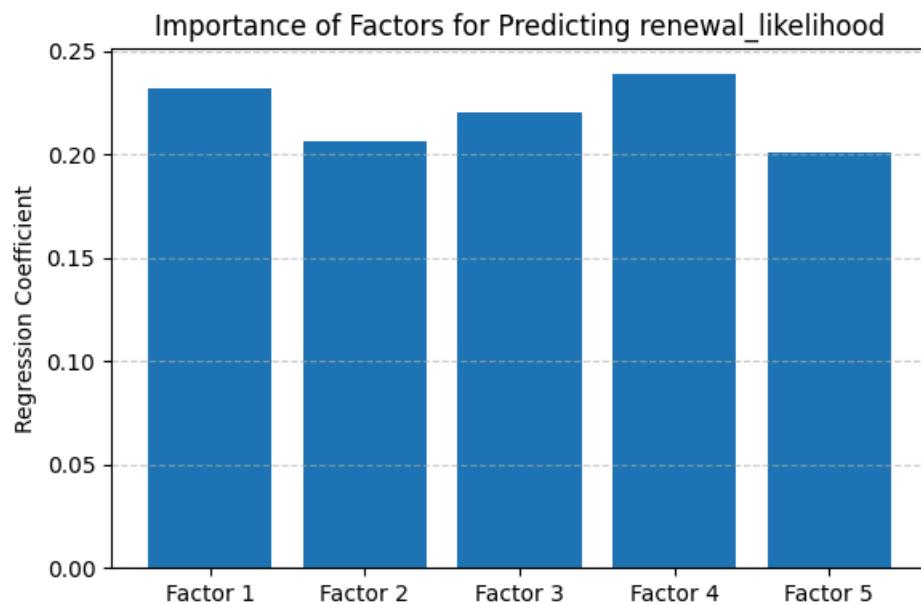

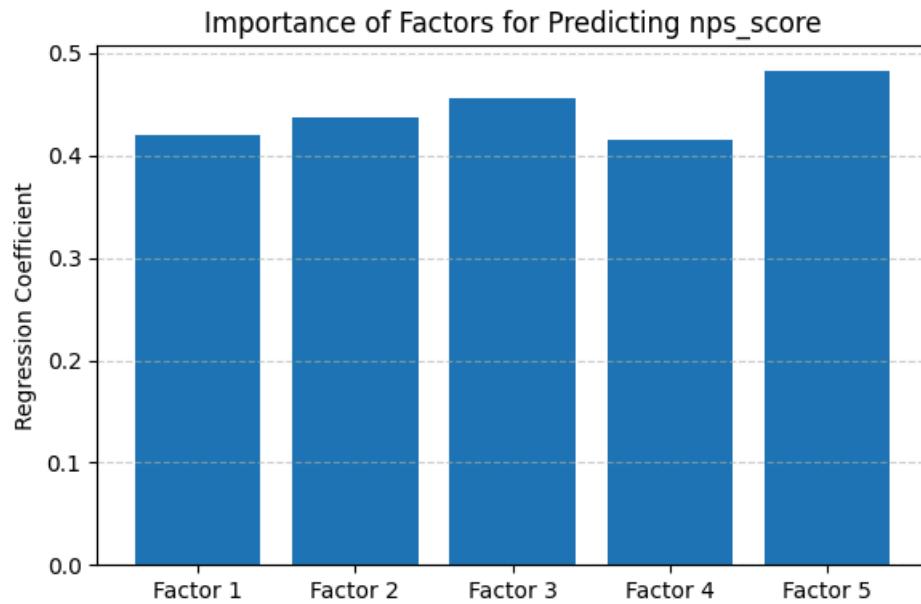

```
In [ ]: factor_scores_df.describe()
```

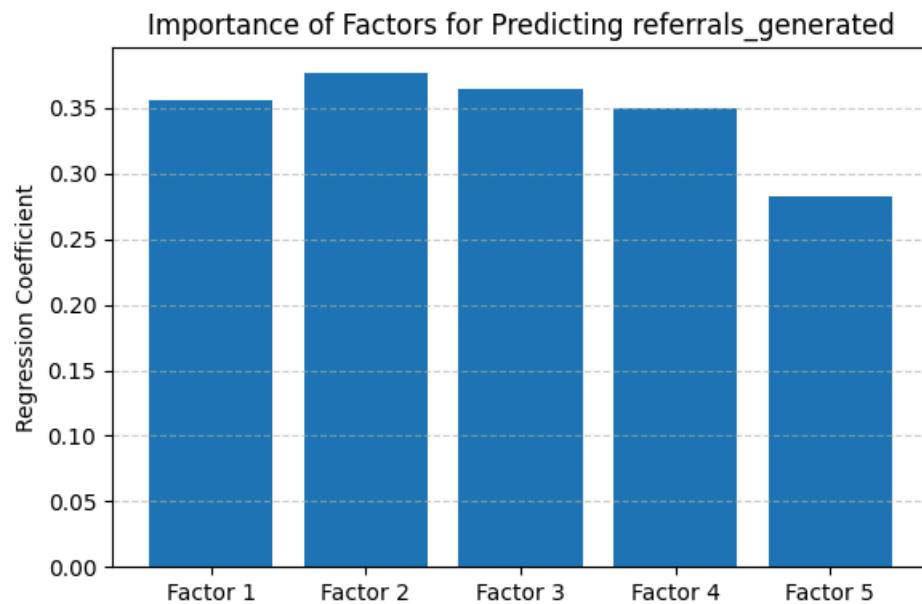

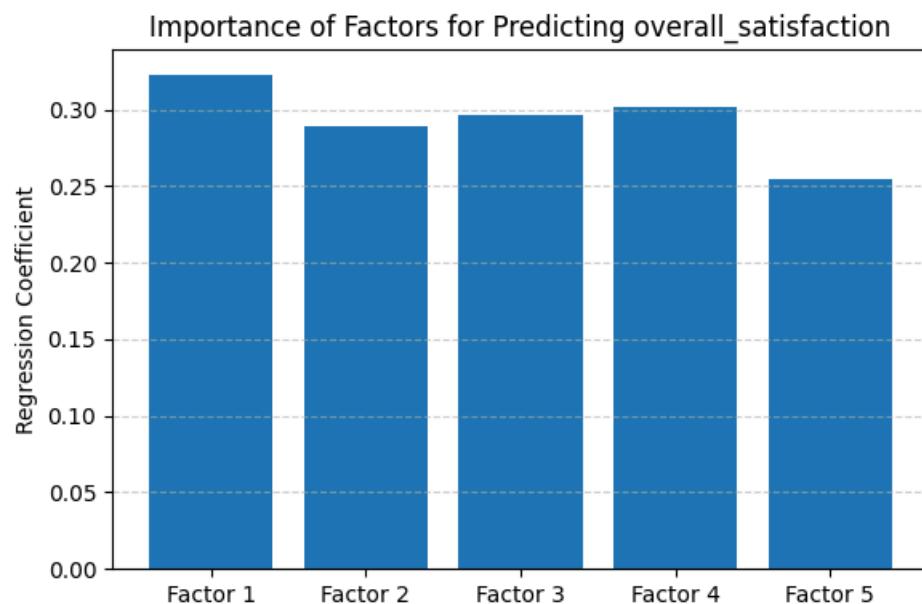

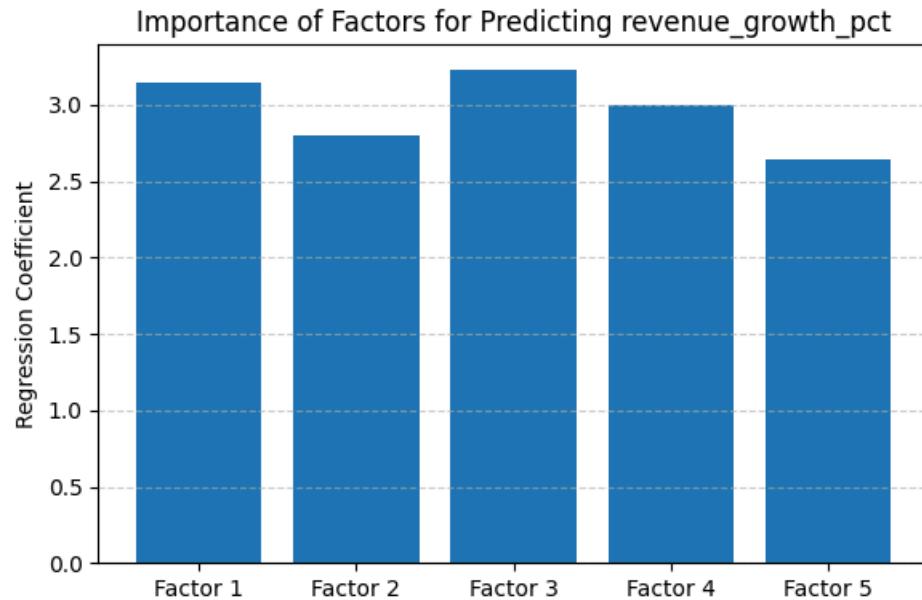

Out[ ]:	Technical Delivery & Solutioning	Relationship & Account Management	Project Execution & Governance	Commercial Value & Pricing	Support, Training & Documentation
<b>count</b>	3.400000e+03	3.400000e+03	3.400000e+03	3.400000e+03	3.400000e+03

```
In [ ]: factor_df = pd.DataFrame(factor_scores, columns=[f"Factor {i+1}" for i in range(factor_scores.shape[1])])
outcomes = ['nps_score', 'renewal_likelihood', 'revenue_growth_pct', 'overall_satisfaction', 'referrals_gene

for outcome in outcomes:
    y = df[outcome].values
    model = LinearRegression().fit(factor_df, y)
    plt.figure(figsize=(6, 4))
    plt.bar(factor_df.columns, model.coef_)
    plt.title(f"Importance of Factors for Predicting {outcome}")
    plt.ylabel("Regression Coefficient")
```

```
plt.grid(axis='y', linestyle='--', alpha=0.6)
plt.tight_layout()
plt.savefig(f'importance_{outcome}.png')
plt.show()
```

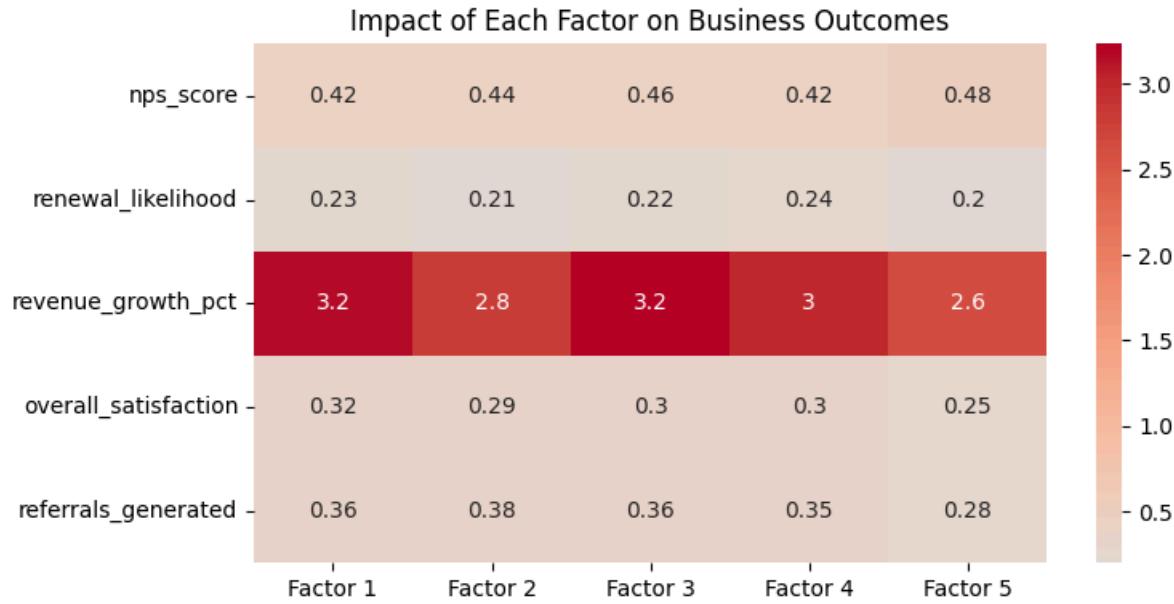

```
In [ ]: coefs = []
outcomes = ['nps_score', 'renewal_likelihood', 'revenue_growth_pct', 'overall_satisfaction', 'referrals_generated']
for outcome in outcomes:
    y = df[outcome].values
    model = LinearRegression().fit(factor_df, y)
    coefs.append(model.coef_)

coef_df = pd.DataFrame(coefs, index=outcomes, columns=factor_df.columns)

plt.figure(figsize=(8, 4))
sns.heatmap(coef_df, annot=True, cmap="coolwarm", center=0)
plt.title("Impact of Each Factor on Business Outcomes")
plt.tight_layout()
plt.savefig('factor_impact_heatmap.png')
plt.show()
```

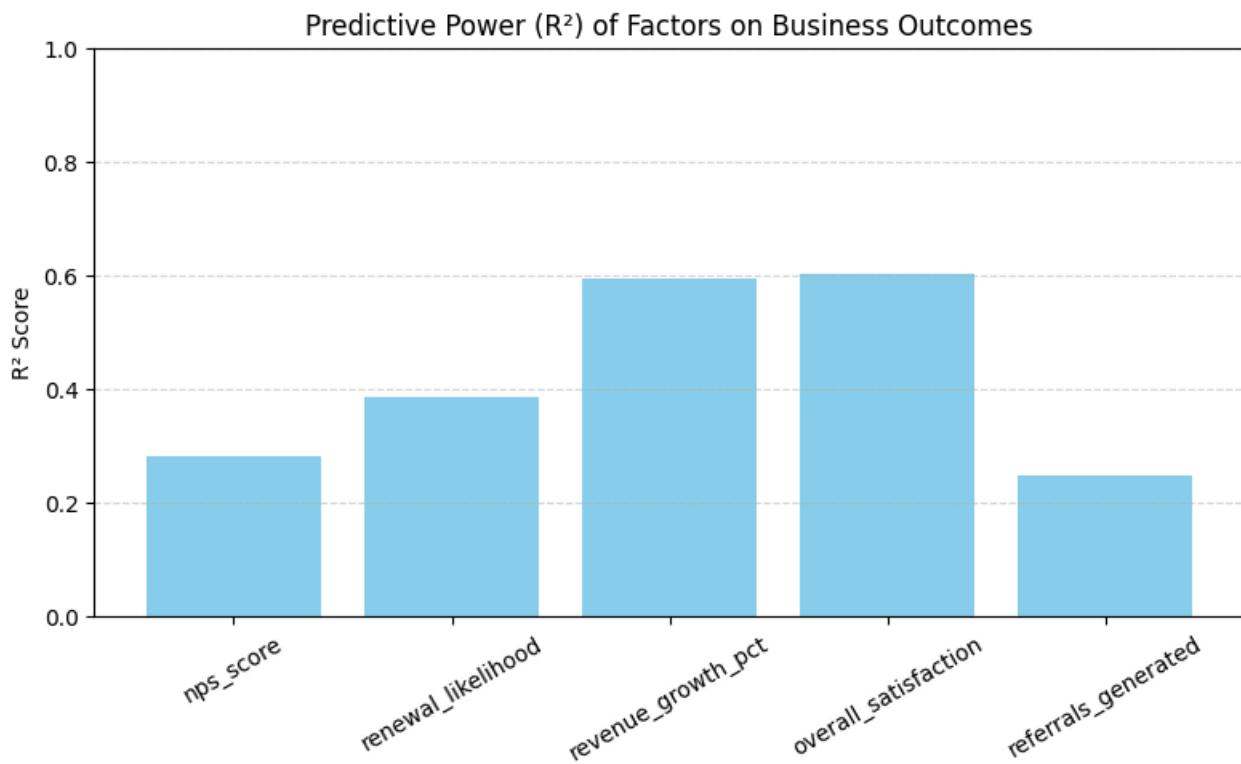

This heatmap shows how each factor affects different business outcomes. The darker and higher the value, the stronger the influence. It helps us see which factors are more important for driving customer results like satisfaction, revenue growth, and loyalty.

```
In [ ]: outcomes = ['nps_score', 'renewal_likelihood', 'revenue_growth_pct', 'overall_satisfaction', 'referrals_generated']

r2_scores = {}

for outcome in outcomes:
    y = df[outcome].values
    model = LinearRegression().fit(factor_df, y)
    r2_scores[outcome] = model.score(factor_df, y)

# Gráfico
plt.figure(figsize=(8, 5))
plt.bar(r2_scores.keys(), r2_scores.values(), color='skyblue')
plt.title("Predictive Power (R2) of Factors on Business Outcomes")
plt.ylabel("R2 Score")
plt.ylim(0, 1)
plt.xticks(rotation=30)
plt.grid(axis='y', linestyle='--', alpha=0.5)
plt.tight_layout()
plt.savefig('predictive_power_factors.png')
plt.show()
```

The bar chart presents the  $R^2$  score for each outcome, which tells us how well the factors explain each business result. Higher bars mean better prediction. The factors predict overall satisfaction and revenue growth very well ( $R^2 \approx 0.6$ ), while nps\_score and referrals\_generated are less explained by the factors.

## Team Information

**Team:** [Team 10]

**Members:**

- [Paulina Díaz Arroyo] (A01029592) - Data exploration and factor extraction
- [Luis Alan Morales Castillo] (A01659147) - Factor interpretation and business insights
- [Rodrigo Jiménez Ortiz] (A01029623) - Visualization and recommendations
